The following Footnote should be inserted on page 8 , where indicated by the asterisk:

It should be emphasized that, above a few MeV, not all of the levels have been identified. This is especially true for the medium weight and heavy nuclei. When not all levels are included, the calculation of the cross section for compound elastic scattering is always an overestimate. Therefore, above  $\sim$  2.5 MeV, the measured elastic scattering differential cross sections should lie between the curves for shape elastic and for shape-plus-compound elastic.

### **Abstract**

Neutron differential elastic scattering cross sections and total cross sections have been calculated for a large number of nuclides at selected energies between 0 and 16 MeV. Comparison is made with experimental data. The elements and energies were selected on the basis of the AEC's Nuclear Cross Sections Advisory Group request compilation.

## INTRODUCTION

The increasing emphasis on nuclear energy during the past decade has spawned increasing requirements for cross sections of neutron interactions with a large number of nuclides and over an energy region extending from thermal to approximately 16 MeV. The cross section requirements are mounting much faster than our ability to satisfy them. It is, therefore, not unreasonable to resort, wherever feasible, to calculations as a temporary substitute for direct measurements.

In recent years, a number of models have proved to be remarkably reliable in reproducing neutron cross sections, both differential and integral. The optical model,<sup>1</sup> in particular, has enjoyed outstanding success. This model predicts differential elastic scattering cross sections, total reaction cross sections, and polarizations. Its utility is, however, marred by at least one perversity of nature. This has to do with so-called compound elastic scattering. From the standpoint of the user of cross section data, all elastic processes have the same significance--the target nucleus acquires kinetic energy only. When one measures the differential elastic cross sections, one measures all elastic processes and this is precisely what is required in application. However, we now know with certainty that at low neutron energies (below  $\sim 5$  MeV), and for essentially all complex nuclei, there occurs a process which involves the formation of a compound nucleus with subsequent decay through the entrance channel. In other words, kinematically it is an elastic scattering process, but functionally it is a nonelastic interaction which proceeds through a compound nucleus. Any realistic model will recognize the above process for what it is--a nonelastic process; and the optical model does just that: it includes compound elastic

scattering in the reaction cross section. However, Hauser and Feshbach have shown how to take it back out again; but to do this, we need to know all the energy levels, and their properties, for all possible excitation energies of the residual nucleus. In general, such data are not available for energies above a few MeV. Above about 5 MeV there are usually so many open channels for decay of the compound nucleus that decay through the entrance channel is negligible, and shape elastic scattering dominates.

In this compendium we have calculated total cross sections and differential elastic scattering cross sections for neutrons on a large number of elements with the purpose of providing some of the information currently required in the nation's atomic energy program, as reflected by the latest edition of the NCSAG request compilation, WASH-1057.

One of the authors (L. Rosen) served a term as a member of NCSAG and has witnessed with dismay the rapid increase in the number of requests for cross section measurements, along with a decrease in the rate at which these requests are being satisfied. What follows is, therefore, an attempt to alleviate this situation by satisfying those requirements which do not require the highest accuracy. In order to permit the user to judge the precision and reliability of the calculations, comparisons are made with experimental data.

A word of caution: Neither the total reaction cross sections nor the differential elastic scattering cross sections can be reliably calculated with the optical model for mass numbers below  $\sim 20$ . However, the optical model calculations should indicate the trends reasonably well, even for light nuclei.

#### CALCULATIONS

All the calculations were made with a local optical model potential, using average parameters. The parameters were obtained from a systematic study of the elastic scattering of polarized protons and from the fitting

of 14-MeV neutron elastic scattering data.<sup>2</sup> The potential so deduced contains six parameters and consists of a real and imaginary central potential and a spin-orbit potential of the Thomas type. The potential has the form:

$$v(r) = -Vf(r) - cWg(r) - v_s h(r) \vec{\sigma} \cdot \vec{l} .$$

The real central potential is assumed to have a radial dependence of the type proposed by Saxon and Woods<sup>3</sup> and is characterized by a radius, R, and a diffuseness, a:

$$f(r) = \left[ 1 + \exp\left(\frac{r - R}{a}\right) \right]^{-1},$$

where  $R = r_0 A^{1/3}$ . The imaginary part of the potential is peaked at the surface and is characterized by a radius, R, and a width, b. It is of the form:

$$g(r) = -4b \frac{d}{dr} \left[ 1 + \exp\left(\frac{r - R}{b}\right) \right]^{-1}.$$

The form of the spin-orbit term is taken as:

$$h(r) = -\frac{\lambda^2}{\pi} \frac{1}{r} \frac{df(r)}{dr} \vec{\sigma} \cdot \vec{l} ,$$

where  $\lambda_\pi$  is the pion (Compton wavelength); and  $\vec{\sigma}$  is the Pauli matrix for the nucleon, with  $s = (\hbar/2)\sigma$ ; and  $\vec{l}$  is the orbital angular momentum in units of  $\hbar$ .

More complete details of the calculational method and the origin of the parameters herein used are given in Ref. 2.

The parameters used are as follows:

|       |                                                                          |
|-------|--------------------------------------------------------------------------|
| $V$   | $= 49.3 - 0.33E$ (MeV); where E is the neutron energy in the c.m. system |
| $W$   | $= 5.75$ MeV                                                             |
| $r_0$ | $= 1.25$ F                                                               |
| $a$   | $= 0.65$ F                                                               |
| $b$   | $= 0.70$ F                                                               |
| $v_s$ | $= 5.5$ MeV                                                              |

Wherever energy levels are known below the incident neutron energy, compound elastic scattering calculations were performed. They are based on the Hauser-Feshbach theory,<sup>4</sup> and the penetrabilities given by the above potential.\*

## RESULTS

Differential cross sections for shape elastic scattering and also for compound elastic scattering (where level structure and parameters are available in the NRC Data Sheets) were calculated at  $\sim 1\text{-MeV}$  intervals in the energy region 0 to 16 MeV. The results are plotted in Figs. 1 - 334 and presented in tabular form on the facing pages. In all of the figures the solid curves represent shape elastic scattering, and the broken curves the sum of shape and compound elastic scattering. It is these latter curves which correspond to experimental elastic scattering measurements. Comparisons with experimental data are made whenever such data are available in BNL-400. These comparisons should help the user to assess the validity and reliability of the calculations. They also provide an empirical indication of how rapidly the cross section for compound elastic scattering diminishes with increasing energy. In general, for medium-weight and heavy nuclei, compound elastic scattering is of negligible significance above 5-MeV incident neutron energy for by then the level density in the residual nucleus is usually sufficiently high that neutron emission through the entrance channel has very small probability.

The differential shape elastic and compound elastic cross sections, labeled  $\sigma_{SE}$  and  $\sigma_{CE}$ , respectively, have been integrated over  $4\pi$  steradians and the resultant partial total cross sections appear below the tables. In addition, the optical model calculations give the total cross section,  $\sigma_T = \sigma_{SE} + \sigma_{CE} + \sigma_{n,n'} + \sigma_{n,2n} + \sigma_{n,p} + \dots$ , and this value is also given beneath the aforementioned tables.

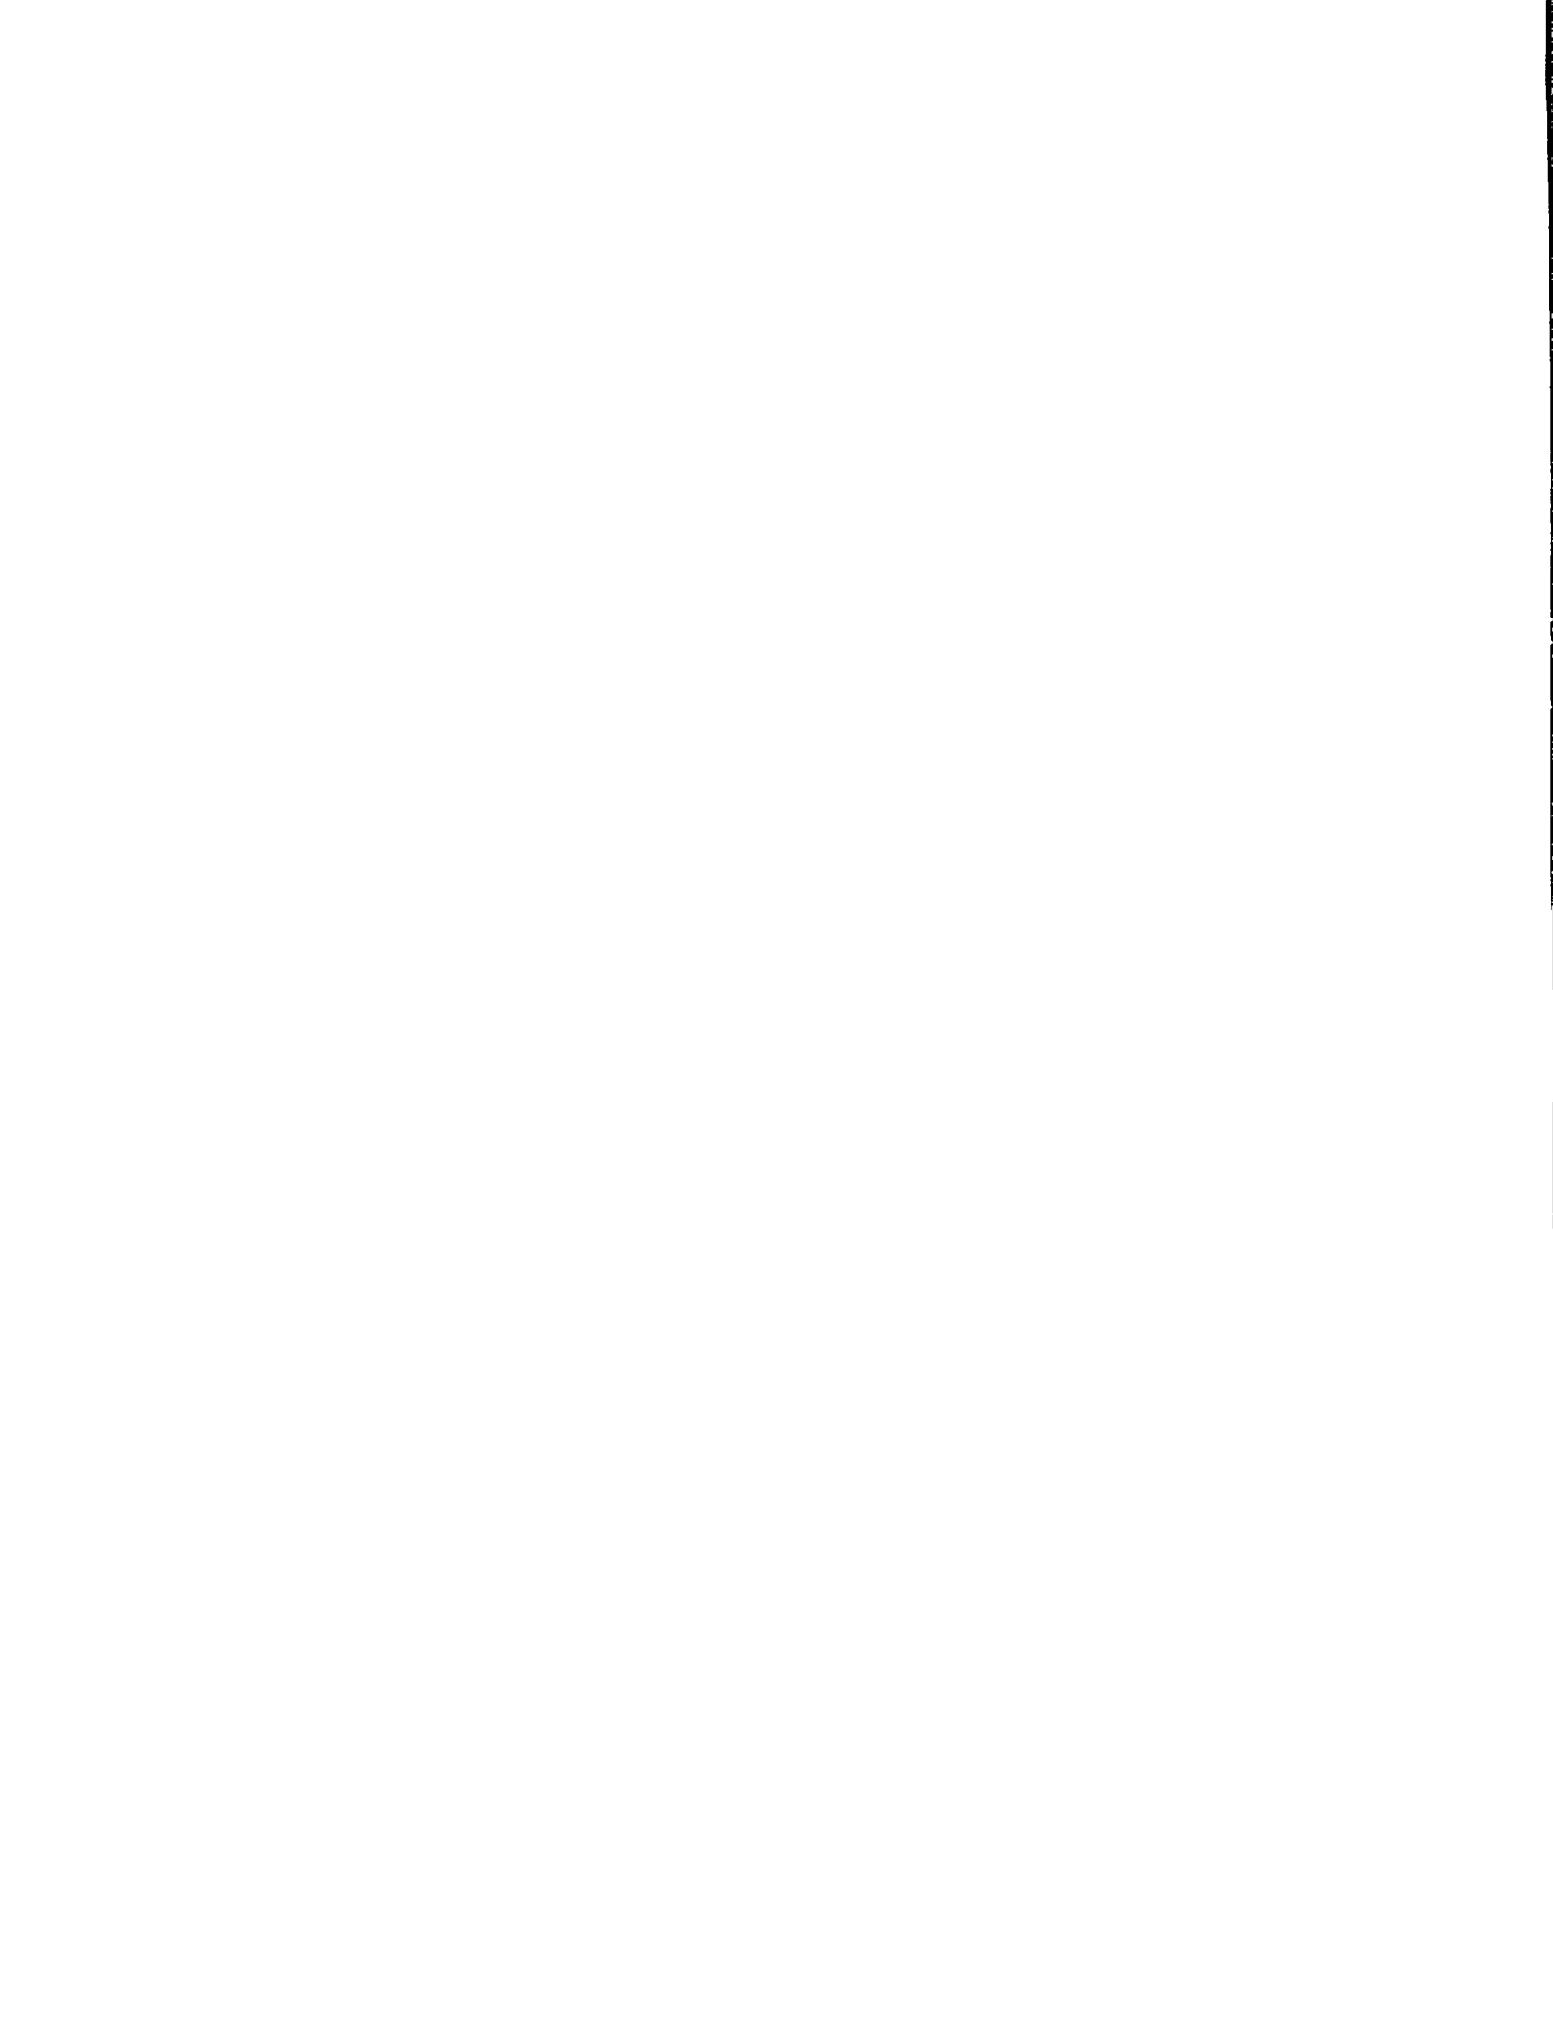

In Figs. 335 to 338 are presented comparisons of total cross section calculations with data compiled in BNL-325 (2nd edition). These comparisons can be used to assess the accuracy of the total elastic and

and total nonelastic cross sections which are derived from the results of the present calculations.

Finally, preceding each set of figures and tables, corresponding to a given element or isotope, are tabulated the energies at which elastic scattering calculations were made as well as the energy levels and level parameters used for the compound elastic scattering calculations.
