TABLES OF ATOMIC WAVE FUNCTIONS

by

V. F. Brattsev

ABSTRACT

Atomic wave functions have been calculated and tabulated for the elements helium through argon, singly and doubly ionized, by the Hartree-Fock-Slater self-consistent-field approximation. The development and applications of that approximation are described.

INTRODUCTION

Quantum mechanics serves as the basis for fundamental modern theories of physical and chemical properties of atoms, molecules, and condensed systems. The task of theoretical calculations of these properties comes, in the final analysis, to the solution of Schrödinger's equation. For the majority of specific problems of atomic physics, knowledge of the ground-state energy of a system and the corresponding wave functions of stationary states is necessary. These data have already made it relatively easy to calculate the entire combination of the optical, electrical, magnetic, and chemical characteristics of these systems.

Unfortunately, the mathematical difficulties of the solution of Schrödinger's equation are such that its exact solution in a final form is practically unattainable. Therefore, in specific calculations we are forced to limit ourselves to approximate solutions with a greater or lesser degree of accuracy. By these means, one can determine the greater value of different types of approximation methods for quantum mechanics.

In approximation methods, specific physical concepts ordinarily are used to permit one to introduce greater or lesser simplification into the general equations of the theory. Because of this, the use of the approximations in comparison with the general theory is limited to the smaller sphere of objectives or phenomena in which the corresponding

simplification is permissible.

Obviously, the simplest class of structured objects of the microcosm accessible to theoretical calculation is that formed by free atoms (we do not take into account atomic nuclei and elementary particles, the theory of which enters into the framework of quantum mechanics). Therefore, in the first year of development, the application and, later, the verification of quantum mechanics were tested on the simplest atoms.

The atomic-wave-function calculations represent the central problem of the theory of atoms and its numerous applications. Atoms, to a considerable degree, retain their individuality in the complex formations of molecules and crystals. Therefore, atomic wave functions are also used in the theory of these complex objects. Hence we understand the scientific interest and also the significance of methods for deriving atomic wave functions.

The stationary equation for atomic hydrogen and its solution were given in 1926 in the initial pages of Schrödinger's first report¹ concerning quantum mechanics. In the same year, Heisenberg² formulated the approximate theory for the helium atom, showing how to treat the cases of ortho- and para-electron states. Later, there appeared a series of articles devoted to the calculation of helium-like atoms, ending with the computation of Hylleraas,³ which was record breaking for that time. There was interest in similar calculations, particularly the questions

in connection with the broad program of experimental research begun by Herzberger, for the determination of the magnitude of radiation displacement of the basic energy levels of the two-electron atom and ions. If it is taken into account that radiation corrections are very small (for example, for the 1^1 s state of helium it is 2×10^{-6} of the energy of that state), it becomes clear that the appropriate calculation becomes exceedingly complicated and laborious.^{4,5}

In 1927, Pauling⁶ made a theoretical estimation of the radii and polarizabilities of many-electron atoms and ions, attributing to each electron a hydrogen-like wave function with a properly selected screening constant. There then followed the calculation of analytical hydrogen-like functions with varying exponential indices.^{7,8} On the basis of such calculations, Slater⁹ constructed empirical rules for the selection of parameters for nodeless, radial, one-electron functions of any atom and molecule. These Slater functions were extensively used in basic calculations for atoms and molecules. Interest in analytical hydrogen-like functions has continued.^{10,11}

The general quantum mechanics method of calculation of one-electron atomic functions and atomic fields was introduced in 1927 by Hartree.¹² Hartree's method is based on the fact that every electron in an atom is represented by its own wave function $\psi_n(q)$, and the contribution $V_n(q)$ to the effective electrostatic field of the atom is defined by the integral:

$$V_n(q) = e \int \frac{|\psi_n(q')|^2}{|q - q'|} dq'.$$

Then the Schrödinger equation for the wave function of the atom is replaced by a system of nonlinear integro-differential equations for one-electron functions, in each of which the operator of the interaction of a given electron, along with all the rest, is given by sums of the integrals of the indicated type. The one-electron wave functions obtained as the result of a solution of a system of equations determines the character of the field in which the electrons are located, i.e., the coefficient of the equations. This characteristic of Hartree's equation is reflected in the name "equations of a

self-consistent field." From the hypothesis of a spherical symmetry of the atomic field after integration over angular variables, the Hartree equations represent a system of ordinary integro-differential equations for radial functions.

In connection with the determination of one-electron wave functions, there is also the problem of constructing general wave functions of a system made up of one-electron functions. In general, this question is connected with the Pauli principle and with the symmetry properties of wave-function coordinates. In 1930, Fock¹³ demonstrated that Hartree's equations could be obtained by modifying the variational derivative of the Schrödinger equation for the many-electron system, if one represents the wave functions of that system in terms of the product of one-electron functions and varies the latter. The product of one-electron functions, generally speaking, does not satisfy requirements of Pauli's proper symmetry principle. Utilizing in the variation principle the wave-function system constructed from the one-electron functions and taking into account Pauli's principle, Fock obtained a system of equations different from Hartree's equations by the presence of supplementary so-called exchange members in the operator of the Coulomb interaction of electrons. These exchange members also determine the separation into terms distinguished by the values of the total spin S and angular momentum L of the electrons.

The equations of the self-consistent field with the Fock exchange give the best description of many-electron systems within the framework of a one-electron approximation as they are derived by variational means with this single simplifying assumption. Therefore, beginning in 1930, a significant number of atomic calculations were carried out by Hartree,^{14,15} his students, and others, using Fock's integral equations. The construction of high-speed calculating machines exerted an influence on the general direction of the calculation of atomic structures. After 15 years, almost all endeavors in this field are devoted to the calculation of analytical wave-function parameters. As Löwdin¹⁶ demonstrated, radial wave functions can be accurately approximated by a linear combination of Slater's functions without node with properly selected indices of exponents and coefficients. Therefore, this form of analytic wave func-

tions was selected by most authors.¹⁷⁻²³ Such a change in the general direction is apparently connected with the fact that until recently, computers possessed a highly restricted memory. The analytic form of the functions permits one to use relatively few data, which is its advantage. As with numerical integration, one has to deal with rather cumbersome tables. However, with increased numbers of shells in the atom, the number of parameters quickly increases and the amount of work necessary for obtaining them also increases, quickly exhausting the capacity of the most powerful computers.

In connection with what has been said in the literature, we again observe the tendency toward the numerical integration of the Hartree and Hartree-Fock equations.²⁴ This is contributed to by the growth in capacity of the memory storage of contemporary computers and also to the development of more perfect methods of numerical integration of differential equations, for example, the method of "dispersion" by elimination of fluctuation.²⁵ Some of the first work devoted to numerical integration of the equation of the self-consistent field done on electronic computers is related in articles cited as Refs. 26-30. Work for the following years is noted in Refs. 31 and 32 and the article cited as Ref. 24.

The Hartree-Fock equations for the structure of heavy atoms contain very unwieldy exchange terms. Their solution demands considerable computer working time, where about 80% of the time is expended on the calculation of exchange interaction. This calculation in heavy atoms plays a comparatively minor role compared with the uncalculated relativistic, spin-orbit-interaction terms. In this case, the value of an energy level is determined to a greater degree by the relativistic terms in the energy operator rather than by the Coulomb exchange interaction. Therefore, in the framework of a nonrelativistic approximation, it would be possible to limit oneself to the solution of the self-consistent field equations without exchange or try to take into account the exchange by a simplified method.

Such an approximate variant of the exchange factors was proposed by Slater.³³ Making use of Slater's simple approximations, Herman and Skillman³⁴ produced voluminous wave-function calculations of the basic states of all the elements from Z=2 to

Z=103. The results of these calculations are published in a separate volume, which, apparently, is the sole extensive publication of atomic wave functions.

However, with the progression to heavy atoms on the basis of the calculations, we must now adopt the one-electron equation of the Dirac type with the self-consistent potential. As we know, only the first steps have been ventured in this direction.

As far as medium and light atoms are concerned, the solution of Hartree-Fock's equation is fully justified. But, at the present time, there do not exist voluminous publications on the wave functions of these atomic calculations in the Hartree-Fock approximation. These tables, to a certain degree, fill that gap.

The tables contain the normalized radial wave functions, $P(n\ell|r)$, of stationary states of atoms and ions and are related to the three-dimensional one-electron wave functions, $\psi(n\ell m|r)$, by the equation

$$\psi(n\ell m|r) = \frac{1}{r} P(n\ell|r) Y(\ell m|j, \phi).$$

The functions $P(n\ell|r)$ are obtained by a numerical solution of the Hartree-Fock equations.

This article contains the results of calculations for all terms of the principal elemental configurations of singly- and doubly-ionized atoms from helium to argon, inclusive.

The form of the tables is traditional. The functions $P(n\ell|r)$ are cited separately for each state of the atom or ion. For the sake of simplicity in the use of the tables, we did not include the columns containing the functions coinciding in limits of accuracy but pertaining to a different state. At the end of each column are given the values of the Lagrange diagonal multipliers $\lambda(n\ell)$ and the mean values of the powers of the variable r ,

$$\langle r^\alpha \rangle = \int_0^\infty r^\alpha P^2(n\ell|r) dr,$$

for $\alpha = -2, -1, 1$, and 2 . All numbers are cited with an accuracy up to the last significant figure.

The method of Hartree-Fock is set forth at length in Ref. 15. We stopped at its last stage; that is, at the numerical determination of the equations of the self-consistent field.

For the atom with the nuclear charge Z in a state belonging to the configuration $(n_1 l_1)^{q_1} \dots (n_s l_s)^{q_s}$ and to any single term, the equations have the form:

$$\left\{ \frac{d^2}{dr^2} + \frac{2(Z - Y)_\sigma}{r} - \frac{l_\sigma(l_\sigma + 1)}{r^2} - \lambda_{\sigma\sigma} \right\} P_\sigma = -\frac{1}{r} \sum_{\sigma' \neq \sigma} \left(\sum_k T_{\sigma\sigma'k} Y_{\sigma'k} - \lambda_{\sigma\sigma'} \right) P_{\sigma'}, \quad (1)$$

$$0 \leq r < \infty, \quad 1 \leq \sigma \leq s,$$

where

$$Y_\sigma = \sum_{\sigma'} (q_{\sigma'} - \delta_{\sigma\sigma'}) Y_{\sigma'\sigma} - \sum_{k>0} T_{\sigma\sigma'k} Y_{\sigma'k},$$

$$Y_{\sigma\sigma'k} = \int_0^r \left(\frac{r}{r'}\right)^k P_\sigma P_{\sigma'} dr' + \int_r^\infty \left(\frac{r}{r'}\right)^{k+1} P_\sigma P_{\sigma'} dr'.$$

The coefficients $T_{\sigma\sigma'k}$ are determined by the configuration and the term. The function $P(n_\sigma l_\sigma | r)$ are briefly designated by P_σ .

Equation (1) represents the condition that the expected value of the total energy be stationary with respect to variations of the functions P_σ and be subject to the supplementary conditions:

$$P_\sigma(0) = P_\sigma(\infty) = 0, \quad (2)$$

$$\int_0^\infty P_\sigma^2 dr = 1, \quad (3)$$

$$\int_0^\infty P_\sigma P_{\sigma'} dr = 0, \text{ then } l_\sigma = l_{\sigma'}, n_\sigma \neq n_{\sigma'}. \quad (4)$$

The parameters, $\lambda_{\sigma\sigma'}$, appear in the calculation of these conditions as Lagrange multipliers, whereupon the diagonal multipliers, $\lambda_{\sigma\sigma}$, correspond to normalization conditions in Eq. (3), and the nondiagonal multipliers, $\lambda_{\sigma\sigma'}$, $\sigma \neq \sigma'$, correspond to orthogonal conditions in Eq. (4). To simplify the task, we delete the last term from the calculation and assume $\lambda_{\sigma\sigma'} = 0$ with $\sigma \neq \sigma'$. As we know, it is possible, in a number of cases, to do this without any disadvantage, as when, for example, all the shells are closed in a configuration. In general, there is a basis for hoping that nondiagonal multipliers can be made so small that they can be disregarded without exerting a significant effect on the solution of the system in Eq. (1). Calculations have shown that

this hope is very often (but unfortunately, not always) justified, and orthogonality conditions are fulfilled to a sufficient degree of accuracy in a natural way. Further, with reference to the system in Eq. (1) we shall always assume the absence of the nondiagonal Lagrangian multipliers.

Thus, the problem consists of searching for a solution to the system in Eq. (1), satisfying conditions in Eqs. (2) and (3), and of belonging to a given configuration. The latter means the following: neither the equations nor the supplementary conditions depend upon the principal quantum number, n_σ , entering into the configuration. It is natural that the system in Eq. (1) may have many solutions satisfying the conditions in Eqs. (2) and (3). There is the further necessity of one additional condition permitting each solution to lead to a specific configuration. To formulate it, we note that each equation of the system in Eq. (1), by obvious substitution of functions P_σ into Y_σ and into the right-hand side, could be made linear and similar with respect to the function corresponding to it:

$$\left\{ \frac{d^2}{dr^2} + \frac{2(Z - Y_\sigma)}{r} - \frac{l_\sigma(l_\sigma + 1)}{r^2} - \lambda_{\sigma\sigma} \right\} P_\sigma = \int_0^\infty K_\sigma(r, r') P_\sigma(r') dr'. \quad (5)$$

Let us agree that:

in order to compute the solution of the system in Eq. (1), suitable additional conditions in Eqs. (2) and (3) belong to the configurations $(n_1 l_1)^{q_1} \dots (n_s l_s)^{q_s}$, if each function P_σ of this solution is the $(n_\sigma - l_\sigma - 1)$ th eigenfunction of the corresponding linear operator in Eqs. (5) and (2). (6)

The problem is solved by the method of successively making the functions more precise. Let there be a certain approximation $\{\tilde{P}_\sigma\}$ with a desired solution $\{P_\sigma\}$. Let us assume that the function made more precise has the index number σ_1 . The used approximate function \tilde{P}_{σ_1} made the equation linear with the index σ_1 . For the new, more precise approximation we shall normalize to unity the $(n_{\sigma_1} - l_{\sigma_1} - 1)$ th eigenfunction of the problem. Having next selected another number, σ_2 , we shall define P_{σ_2} , etc. The approximate zero must be prepared beforehand and may be established by different methods as, for instance,

by means of analytical functions or the interpolative method of Hartree. It is simpler to assume that all $P_\sigma = 0$. If it is agreed to begin with the functions of the inner shells and move in the direction of the outer shells, then the approximation will not be bad.

The $(n_\sigma - l_\sigma - 1)$ th eigenfunction and the corresponding eigenvalue of the problem in Eqs. (5) and (2) in its turn is usually found by the method of successive approximation: the $(m+1)$ approximation is $P_\sigma^{(m+1)}$, and $\lambda_\sigma^{(m+1)}$ is found through approximation from the equation (the index σ decreases):

$$\left\{ \frac{d^2}{dr^2} + \frac{2(z - r^{(m)})}{r} - \frac{\ell(\ell + 1)}{r} \right\} P^{(m+1)} = \lambda^{(m+1)} P^{(m+1)} + \int K^{(m)}(r, r') P^{(m+1)}(r') dr' , \quad (7)$$

provided that

$$P^{(m+1)}(0) = P^{(m+1)}(\infty) = 0$$

and for any condition of normalization. Functions $P^{(m)}$ are normalized provided that all normalizations of m are done in the same manner. If it is necessary in achieving the solution, it is possible to renormalize by virtue of the uniformity of the problem in Eqs. (5) and (2). In practice, it is convenient [Eq. (3)] to normalize functions to unity at some point r_1 :

$$P(r_1) = 1.$$

Thus, at each successive approximation one must find such a λ and, corresponding to it, its solution P of the equation:

$$\frac{d^2P}{dr^2} + FP = \lambda P + Q, \quad (8)$$

if

$$P(0) = P(\infty) = 0 \quad (9)$$

and

$$P(r_1) = 1. \quad (10)$$

Let $P_o(r, \lambda)$ be the solution of Eq. (8) satisfying the supplementary conditions

$$P_o(0, \lambda) = 0, \quad P_o(r_1, \lambda) = 1.$$

At the point r_2 , where $r_2 > r_1$, the function P_o acquires a certain value $P_o(r_2, \lambda)$. We shall now determine the function $P_\infty(r, \lambda)$ as a solution of Eq. (8) with the conditions

$$P_\infty(r_2, \lambda) = P_o(r_2, \lambda), \quad P_\infty(\infty, \lambda) = 0.$$

With $h > 0$ and fixed values r_1 and r_2 , the expression

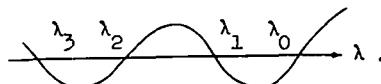

$$w(\lambda) = \frac{1}{h} \{ P_o(r_2 + h) - P_\infty(r_2 + h) \}$$

represents a certain function λ . It is obvious that those λ 's, for which the solution of Eq. (8) with zero conditions at the boundaries of Eq. (9), satisfying the conditions of normalization in Eq. (10), will be the roots of the equation

$$w(\lambda) = 0. \quad (11)$$

The sought λ is distinguished from the other roots by the fact that the solution of Eq. (8) $(n - l - 1)$ is once converted into zero in the interval (r_1, r_2) . With the corresponding choice of r_1 and r_2 (at which we later stop), this is equivalent to the condition in Eq. (6).

If the unknown root is separated from the rest by the values λ' and λ'' , it is easily found to an assigned degree of accuracy by the chord method. The boundaries λ' and λ'' are found by successive trials. In the progression from one trial value to the next, one can be guided by the fact that the trial value must be increased if the number of nodes is greater than $n - l - 1$ at the function P_o , and decreased if the number of nodes is less than $n - l - 1$. If the number of nodes is equal to $n - l - 1$, the direction of change of the trial λ can be defined by the symbol $w(\lambda)$. The function $w(\lambda)$ is constant with respect to λ , and, if λ is sufficiently large, then $w(\lambda) > 0$. Thus the graph of the function $w(\lambda)$ appears as:

It is obvious that for a located root with an even number, the trial value λ must be increased when $w < 0$ and decreased when $w > 0$. If the sought root has an uneven number, then the process must be reversed. Roots are computed by means of numerical starting with a large number to which has been attributed a neutral number. This rule is easy to express analytically:

$$\lambda' = \lambda \left\{ 1 + \alpha_1 \frac{\text{sign}(\xi - n + l + 1)}{n} \right\}, \quad (12)$$

when $\xi \neq n - l - 1$ and

$$\lambda' = \lambda \left\{ 1 + \alpha_2 \frac{(-1)^{n-1} \text{sign } w(\lambda)}{n} \right\}, \quad (13)$$

if $\xi = n - l = 1$. Here ξ is the number-changing sign at the function P_0 in the interval (r_1, r_2) , but α_1 and α_2 are positive constants determining the magnitude of change of experimental λ values.

This completes one step in the sequence of making the functions more precise.

At each such step it is necessary to calculate the functions

$$F = F_\sigma = \frac{2(Z - Y_\sigma)}{r} - \frac{l_\sigma(l_\sigma + 1)}{r^2} - \lambda_{\sigma\sigma},$$

$$Q = Q_\sigma = -\frac{1}{2} \sum_{\sigma' \neq \sigma} P_{\sigma'} \sum_k T_{\sigma'\sigma'k} Y_{\sigma'\sigma'k},$$

which in the main comes down to the calculation of $Y_{\sigma'\sigma'k}$. Designated by $Z_{\sigma'\sigma'k}$ the first item in Eq. (1) for $Y_{\sigma'\sigma'k}$ is:

$$Z_{\sigma'\sigma'k} = \frac{1}{r^k} \int_0^r r^k P_\sigma P_{\sigma'} dr.$$

It is obvious that $Z_{\sigma'\sigma'k}(0) = 0$ and $Z_{\sigma'\sigma'k} \rightarrow 0$ as $r \rightarrow \infty$. By direct differentiation we are satisfied that

$$Z'_{\sigma'\sigma'k} = -\frac{k}{r} Z_{\sigma'\sigma'k} + P_\sigma P_{\sigma'},$$

$$Y'_{\sigma'\sigma'k} = \frac{k+1}{r} Y_{\sigma'\sigma'k} - \frac{2k+1}{r} Z_{\sigma'\sigma'k}.$$

By such means, the calculation $Y_{\sigma'\sigma'k}$ is arrived at by successive integrations of equations of the first order.¹⁵ From consideration of stability, the first of these is integrated from 0 to ∞ for the beginning condition $Z_{\sigma'\sigma'k} = 0$; the second, in the converse direction, whereupon $Y_{\sigma'\sigma'k} = Z_{\sigma'\sigma'k}$ as $r \rightarrow \infty$.

A peculiarity for $r = 0$ in Eq. (1) makes a varying r an inconvenient numerical realization of the described method. In the first place, it is complicated to use the formulas of integral equations; in the second place, the integration step has to be changed numerous times. These tend to violate the process of the operation cycles, blocking programs and significantly increasing their size.

One way to surmount these difficulties is to substitute appropriate variables. One could expect that a good variable would be

$$\rho = r + \ln r. \quad (14)$$

Actually, as $r \rightarrow \infty$ the equations for P are close to the equations for the exponents and, therefore, there is no reason to change the step of integration by means of larger r 's. Accordingly, P for the larger r 's is almost equal to r . For $r \sim 0$, $P \sim r^{l+1}$. As in the case of $\rho \sim \ln r$, then, relative to the variable ρ , $P \sim e^{(l+1)\rho}$ and it is again not necessary to change the step of integration according to ρ . By such means, to make use of variable ρ , the step could be taken by means of a constant both as $\rho \rightarrow \infty$ and as $\rho \rightarrow -\infty$.

The substitution of only one independent variable in the equation for functions P would keep the first derivative, which is undesirable. Therefore, there follow substitutions by means of an independent variable to combine with substitution function P . In accordance with Ref. 14, we assume:

$$f = \left(\frac{r}{1+r}\right)^{-\frac{1}{2}} P(r).$$

It is not difficult to reason that through such a transformed equation for P ,

$$\frac{d^2P}{dr^2} + FP = Q$$

is changed into

$$\begin{aligned} \frac{d^2f}{dp^2} + \frac{r^2}{(1+r)^2} \left\{ r^2 F - \frac{1}{(1+r)^2} \left(r + \frac{1}{4}\right) \right\} f \\ = \left(\frac{r}{1+r}\right)^{\frac{3}{2}} Q, \end{aligned} \quad (15)$$

for function f , and the equations for $Z_{\sigma'\sigma'k}$ and $Y_{\sigma'\sigma'k}$ assume the aspect

$$\begin{aligned} Z'_{\sigma'\sigma'k} &= -\frac{k}{1+r} Z_{\sigma'\sigma'k} + \frac{r^2}{(1+r)^2} f_\sigma f_{\sigma'}, \\ Y'_{\sigma'\sigma'k} &= \frac{k+1}{1+r} Y_{\sigma'\sigma'k} - \frac{2k+1}{1+r} Z_{\sigma'\sigma'k} \end{aligned} \quad \left. \right\} \quad (16)$$

Additional conditions are:

$$f(-\infty) = f(+\infty) = 0,$$

$$\int_{-\infty}^{+\infty} \left(\frac{r}{1+r}\right)^2 f^2 dr = 1.$$

The first approximation which must be done in the numerical derivation is the substitution of the numerous intervals for the final: $\rho_- \leq \rho \leq \rho_+$. Thus, it is necessary to remove the boundary condition from

$\pm \infty$ at points p_{\pm} . For us it will be sufficient to know the rough equations

$$q_+ = \frac{f_\infty(p_+ + h)}{f_\infty(p_+)}, \quad q_- = \frac{f_0(p_- - h)}{f_0(p_-)}. \quad (17)$$

To find them, it is possible to take advantage of the method suggested by Hartree.¹⁵

The boundary condition $Z(-\infty) = 0$ could similarly be removed. But inasmuch as Z decreases significantly more rapidly than f as $p \rightarrow -\infty$, it is possible, without disadvantage, simply to assume $Z(p_-) = 0$. For the function Y , the initial value pertains to the point p_+ :

$$Y(p_+) = Z(p_+).$$

The second approximation consists of substituting a different differential equation. For the solution of equations of the first order, we take advantage of the formula

$$Y_{i+3} = Y_{i+2} + \frac{h}{24} (9Y'_{i+3} + 19Y'_{i+2} - 5Y'_{i+1} + Y'_i),$$

and for the second equation, the formula

$$Y_{i+1} - 2Y_i + Y_{i-1} = \frac{h^2}{12} (Y''_{i+1} + 10Y''_i + Y''_{i-1}). \quad (18)$$

Substituting in their derivatives, given in the equations, we obtain a convenient form for programming formulas:

$$\begin{aligned} Z_i &= \frac{1}{1 + \frac{9kh}{24(1+r_i)}} \left\{ \left[1 - \frac{19kh}{25(1+r_{i-1})} \right] Z_{i-1} \right. \\ &\quad \left. + \frac{5khZ_{i-2}}{24(1+r_{i-2})} - \frac{khZ_{i-3}}{24(1+r_{i-3})} + \frac{9hr_i^2 R_i}{24(1+r_{i-1})^2} \right. \\ &\quad \left. + \frac{19hr_{i-1}^2 R_{i-1}}{24(1+r_{i-1})^2} - \frac{5hr_{i-2}^2 R_{i-2}}{24(1+r_{i-2})^2} + \frac{hr_{i-3}^2 R_{i-3}}{24(1+r_{i-3})^2} \right\}, \end{aligned} \quad (19)$$

$$\begin{aligned} Y_i &= \frac{1}{1 + \frac{9h(k+1)}{24(1+r_i)}} \left\{ \left[1 - \frac{19h(k+1)}{24(1+r_{i+1})} \right] Y_{i+1} \right. \\ &\quad \left. + \frac{5h(k+1)Y_{i+2}}{24(1+r_{i+2})} - \frac{h(k+1)Y_{i+3}}{24(1+r_{i+3})} + \frac{9h(k+1)Z_i}{24(1+r_i)} \right. \\ &\quad \left. + \frac{19h(2k+1)Z_{i+1}}{24(1+r_{i+1})} - \frac{5h(2k+1)Z_{i+2}}{24(1+r_{i+2})} + \frac{h(2k+1)Z_{i+3}}{24(1+r_{i+3})} \right\}, \end{aligned} \quad (20)$$

where

$$R_i = R_{\sigma, \sigma', i} = f_{\sigma, i} f_{\sigma', i}$$

and

$$\begin{aligned} \left(1 + \frac{h^2 F_{i+1}}{12} \right) f_{i+1} - \left(2 - \frac{5h^2 F_i}{6} \right) f_i + \left(1 + \frac{h^2 F_{i-1}}{12} \right) f_{i-1} \\ = - \frac{h^2}{12} (\bar{Q}_{i+1} + 10\bar{Q}_i + \bar{Q}_{i-1}), \\ \bar{Q}_i = \left(\frac{r_i}{1+r_i} \right)^{\frac{3}{2}} Q_i. \end{aligned} \quad (21)$$

Formulas in Eqs. (19) and (20) require knowledge of the three initial values of Z and Y . In accordance with the accepted method of eliminating boundary conditions,

$$Z_{-3} = Z_{-2} = Z_{-1} = 0$$

and

$$Y_N = Z_N, \quad Y_{N-1} = Z_{N-1}, \quad Y_{N-2} = Z_{N-2},$$

where the zero index corresponds to point p_- , and index N , to point p_+ .

For the construction of functions f_0 and f_∞ (corresponding to P_0 and P_∞), it is necessary first of all to choose points p_1 and p_2 corresponding to points r_1 and r_2 . For such points it is convenient to take those values of the argument p for which the f coefficient in Eq. (15) is reduced to zero. It can be demonstrated that there are always two such values of the argument.

In the interval $[p_1, p_2]$, both solutions of Eq. (15) oscillate, but in the interval $[p_-, p_1]$ and $[p_2, p_+]$, one increases and the other decreases. Therefore, in different intervals, the calculation of functions has to be carried out differently. In the interval $[p_-, p_1]$, the function f_0 is found by the method of "dispersion"²⁵ in its utilization with different equations [Eq. (21)]. By induction, we see that the values for $f_{0,i}$ and $f_{0,i+1}$ are allied in the relationship:

$$f_{0,i} = u_0(i, i+1) f_{0,i+1} + u_0(i, i), \quad (22)$$

in which

$$u_0(i, i+1) = \frac{A_{i+1}}{2B_1 - A_1 u_0(i-1, i)}, \quad (23)$$

$$u_0(i, i+1) = \frac{A_{i+1} u_0(i-1, i) + w_i}{2B_1 - A_{i-1} u_0(i-1, i)}, \quad (24)$$

where

$$A_i = 1 + \frac{h^2 F_i}{12}, \quad 2B_i = 2 - \frac{5h^2 F_i}{6},$$

$$w_i = \frac{h^2}{12} (\tilde{Q}_{i+1} + 10\tilde{Q}_i + \tilde{Q}_{i-1}).$$

According to the method of removal of boundary conditions in Eq. (17),

$$\begin{aligned} v_o(-l, 0) &= q_-, \\ u_o(-l, 0) &= 0. \end{aligned}$$

From these initial equations, we calculate $v_o(i, i+1)$ and $u_o(i, i+1)$ according to the recurrence formulas in Eqs. (23) and (24) down to point ρ_1 ; more precisely, until the ρ_1 is near the node point. Since $f_o(\rho_1) = 1$, in all points of the interval $[\rho_-, \rho_1]$, the values of the sought function can be found by means of the formula in Eq. (22). Knowing f_o at the points ρ_1 and $\rho_1 - h$, its value in the interval $[\rho_1, \rho_2]$ can be found very well through the formula

$$f_{o,i+1} = \frac{2B_i f_{o,i} - A_{i-1} f_{o,i-1} + w_i}{A_{i+1}}$$

down to the point $\rho_2 + h$. Along the way are located a number of step changes of function f_o . In the interval $[\rho_2, \rho_3]$, the function f_∞ is found by the dispersion method.

Having obtained $f_o(\rho_2 + h)$ and $f_2(\rho_2 + h)$ by such means, it is possible to calculate $w(\lambda)$, and this is all that is necessary for the solution of the equation $w(\lambda) = 0$.

Coefficients of Eqs. (15) and (16) are expressed by the variable r . Therefore, for their calculations at a fixed value ρ , it is necessary first of all to calculate the corresponding $r(\rho)$, which is obviously arrived at with the solution of the equation

$$\varphi(r) = r + \ln r - \rho = 0. \quad (25)$$

Inasmuch as it is impossible to express r by ρ analytically, we are obliged to resort to the numerical method. It is convenient to apply Newton's method to Eq. (25):

$$r^{(p+1)} = r^{(p)} - \frac{\varphi(r^{(p)})}{\varphi'(r^{(p)})}.$$

$\varphi(r)$ is substituted here and

$$\varphi'(r) = 1 + \frac{1}{r},$$

yielding

$$r^{(p+1)} = r^{(p)} \left(1 + \frac{\rho - r^{(p)} - \ln r^{(p)}}{1 + r^{(p)}} \right).$$

It is evident that

$$\frac{r^{(p+1)} - r^{(p)}}{r^{(p)}} = \frac{\rho - r^{(p)} - \ln r^{(p)}}{1 + r^{(p)}},$$

therefore, if the calculation of r is completed according to the inequality

$$\left| \frac{\rho - r^{(p)} - \ln r^{(p)}}{1 + r^{(p)}} \right| < \epsilon,$$

the sought-for value of r will be known with a fixed relative error ϵ . The initial approximation for r can be obtained from the following considerations. For sufficiently large positive ρ , $r \sim \rho + \ln \rho$. For sufficiently large negative ρ , $r \sim e^\rho$. For an intermediate ρ , r is approximated by $r \approx a + bp + cp^2$.
